Preface

I would like to thank Brita Bye, Ådne Cappelen, Bodil M. Larsen and Birger Strøm for valuable comments and constructive meetings in the process of generating the model documented in this paper. A special thank goes to Birger Strøm for having programmed the model in TROLL. He has also carried out the simulations and contributed substantially to Appendix B. Any remaining errors and shortcomings are mine.

Abstract

A new consumer demand system for the MSG model is documented. Altogether there are 27 basic commodities. The modelling of the allocation system is based on a utility tree approach. Four different branches are involved: *Groceries*, *Housing*, *Transport* and *Other goods and services*. The complete allocation model and the values of all its parameters are documented. The parameters are obtained by combining estimation and calibration. To investigate the properties of the model we calculate expenditure and price elasticities (both uncompensated and compensated) by simulation. Since the elasticities depend on the year in which they are evaluated, they are reported for a selection of years, 2060 being the ultimate one.

1. Introduction

This paper contains technical documentation of an estimated/calibrated consumer demand system to be used in conjunction with the general equilibrium model, MSG 6. The consumer demand system is based on a nested Stone-Geary utility function. In contrast, earlier demand systems have been based on a nested utility function with origo-adjusted CES-functions.¹ The parameters in this latter system were calibrated drawing on information from different data sources. The consumer budget surveys conducted by Statistics Norway were important sources. The parameter values used in the model documented in this paper are only based on National Accounts (NA) data. It has not been common before to use NA data at such a detailed level as in the current paper. It is still an open question how good such data are for quantifying structural parameters.

The paper is disposed as follows. In Section 2 we look at a three-level Stone-Geary utility function and provide the different structural equations which are the basis of estimating/calibrating the parameters involved. Of special concern is the link between the different allocation levels. As is customary in conjunction with utility-tree based models, one starts at the bottom of the utility tree and proceeds to higher levels from there. In Section 3 we apply the general setup on the consumer commodities present in the MSG 6 model. We distinguish between four branches: *Food etc.*, *Housing etc.*, *Transport etc.* and *Others*, see Figure 1. Within the branches we have up to 2 allocation stages. Furthermore we have an allocation stage in which total expenses are allocated to the four branches. All the applied parameter values are reported in this section. In Appendix C we write out all the equations of the consumer block in the notation used in conjunction with the MSG model. Within this block it is explicitly stated which variables are endogenous and which variables are exogenous. In Section 4 we calculate price and expenditure elasticities numerically by shift analysis. The shift analysis is carried out after having added residuals. The constructed consumer demand system should be viewed as a point of departure for further analysis. From a quantitative point of view 27 basic consumer commodities imply a rather comprehensive demand system. The traditional way of dealing with this feature is to impose some type of separability assumptions such that a dimension reduction is obtained. Alternatively, one could try to work with all commodities together using a parsimonious structure of the non-systematic part of the demand functions, cf. for instance de Boer and Harkema (1986, 1997) and de Boer et al. (1996). Econometric quantification of parameters also requires that the parameter values are in the feasible set. This is challenge that has to be dealt with. The parameters are partly estimated and partly calibrated. How reasonable the parameters are may partly be viewed in light of the elasticities they lead to. In conjunction with long-run simulations global properties of the demand equations are an important feature. The elasticities depend on the level of the variables, and accordingly we calculate elasticities for different years.

¹ Cf. for instance Aasness and Holtsmark (1993, 1995) and Bye et al. (2008).

2. Modelling framework²

Let us assume that we have four consumption branches which we label X, Y, Z and W, respectively. We start out by assuming that the amount of money allocated to these four branches is exogenously given and we focus on the allocation of money within the branches. In the following we focus on the X-branch. The treatment of the other branches is analogous to the treatment of the X branch. We assume that there are two allocation stages within the X branch. Let n_X be the number of basic consumer categories at the lower allocation stage (referred to as stage 2) and let m_X be the number of basic consumption categories at the upper stage (referred to as stage 1). Let X_i^2 , $i=1, \dots, n_X$ be the consumption of category i at the lower level (i.e., level 2) within branch X and let the associated price index be denoted PX_i^2 . Total expenditure at the lower level is given by

$$(1) VX^2 = \sum_{i=1}^{n_X} PX_i^2 X_i^2.$$

² This section is especially inspired by Michalek and Keyzer (1992).

We assume for now that VX^2 is exogenously given and that the volumes at this allocation stage are determined according to a linear expenditure system augmented with demographic effects. The demand system, in volume form, is given by

$$(2) X_i^2 = \gamma_{X0i}^2 N + \gamma_{X1i}^2 NC + \frac{\beta_{Xi}^2}{PX_i^2} \left[VX^2 - \sum_{j=1}^{n_X} PX_j^2 (\gamma_{X0j}^2 N + \gamma_{X1j}^2 NC) \right], i = 1, \dots, n_X,$$

where

$$(3) \sum_{j=1}^{n_X} \beta_{Xj}^2 = 1.$$

In (2) N and NC denote, respectively, the total number of persons (in 100 persons) and the total number of persons not older than 19 years (in 100 persons).³ The parameters $\beta_{X1}^2, \dots, \beta_{Xn_X}^2$ are termed marginal budget shares and $\gamma_{X01}^2, \gamma_{X11}^2, \dots, \gamma_{X0n_X}^2, \gamma_{X1n_X}^2$ are parameters characterizing the necessity consumption. They are all unknown and need to be quantified.

To estimate the parameters we transform the system (1) such that the budget shares occur on the left hand side of the equations and then add additive error terms.⁴ Since adding-up is fulfilled the error vector will have a singular covariance matrix and we proceed by estimating the parameters $\beta_{Xi}^2 (i = 1, \dots, n_X - 1)$, $\gamma_{X0i}^2 (i = 1, \dots, n_X)$ and $\gamma_{X1i}^2 (i = 1, \dots, n_X)$ by iterative multivariate non-linear least squares using the $n_X - 1$ first equations in (1), assuming that the $(n_X - 1) \times (n_X - 1)$ covariance matrix of the errors is positive definite, and unconstrained beyond symmetry. The remaining parameter, β_{X,n_X}^2 , is estimated utilizing (3).

The predicted value of the outlay in conjunction with the “necessity consumption”⁵ is

$$(4) VZN^2 = \sum_{i=1}^{n_X} PX_i^2 (\gamma_{X0i}^2 N + \gamma_{X1i}^2 NC), i = 1, \dots, n_X.$$

In light of duality theory we may decompose VX^2 as

$$(5) VX^2 = VZN^2 + PU_X^2 \times U_X^2,$$

where

$$(6) PU_X^2 = \prod_{j=1}^{n_X} (PX_j^2)^{\hat{\beta}_{Xj}^2}$$

and

$$(7) U_X^2 = \left[\prod_{j=1}^{n_X} \left(\frac{1}{\hat{\beta}_{Xj}^2} \right)^{\hat{\beta}_{Xj}^2} \right] \prod_{j=1}^{n_X} (X_j^2 - \hat{\gamma}_{Xj}^2)^{\hat{\beta}_{Xj}^2},$$

where

³ Cf. Pollak and Wales (1981) for consumer demand systems and demographic variables. See also Lewbel (1985) and Pollak and Wales (1992).

⁴ In Appendix A we show this in more detail. The procedure is analogous for the later submodels that are also esimated by ML.

⁵ We write this term in apostrophes since it originally was used in a context with only positive minimum quantities, while we also allow for negative minimum quantities.

$$(8) \hat{\gamma}_{xj}^2 = \hat{\gamma}_{x0j}^2 N + \hat{\gamma}_{x1j}^2 NC, j = 1, \dots, m_X.$$

In (6)-(8) above and below we follow the convention of letting a $\hat{\cdot}$ denote a parameter estimate or a predicted value of a linear combination of parameter estimates with weights based on values of observed variables.

We label U_X^2 in Eq. (7) the (estimated) utility aggregate associated with the lower allocation level in branch X.

At the upper allocation level within branch X we will now determine the optimal values of $X_1^1, \dots, X_{m_X}^1$ together with the optimal value of U_X^2 . The total outlay on the basic commodities $X_1^1, \dots, X_{m_X}^1$ and U_X^2 is given by

$$(9) VXC^1 = \sum_{j=1}^{m_X} PX_j^1 \times X_j^1 + PU_X^2 \times U_X^2.$$

It is also convenient at this stage to introduce

$$(10) VX = VXC^1 + VXN^2,$$

which corresponds to the total outlay on the commodities in branch X.

We now consider the allocation system at the upper level in branch X. Again we use the linear expenditure system augmented with demographic effects

$$(11) X_i^1 = \gamma_{X0i}^1 N + \gamma_{X1i}^1 NC + \frac{\beta_{Xi}^1}{PX_i^1} \left[VXC^1 - \sum_{j=1}^{m_X} PX_j^1 (\gamma_{X0j}^1 N + \gamma_{X1j}^1 NC) - PU_X^2 (\gamma_{X0U_X^2}^1 N + \gamma_{X1U_X^2}^1 NC) \right], \\ i = 1, \dots, m_X,$$

$$(12) U_X^2 = \gamma_{X0U_X^2}^1 N + \gamma_{X1U_X^2}^1 NC + \frac{\beta_{XU_X^2}^1}{PU_X^2} \left[VXC^1 - \sum_{j=1}^{m_X} PX_j^1 (\gamma_{X0j}^1 N + \gamma_{X1j}^1 NC) - PU_X^2 (\gamma_{X0U_X^2}^1 N + \gamma_{X1U_X^2}^1 NC) \right],$$

where

$$(13) \sum_{j=1}^{m_X} \beta_{Xj}^1 + \beta_{U_X^2}^1 = 1,$$

and where the parameters in (13) together with

$$\gamma_{X0i}^1, \gamma_{X1i}^1 (i = 1, \dots, m_X), \gamma_{X0U_X^2}^1 \text{ and } \gamma_{X1U_X^2}^1$$

are parameters to be estimated. To quantify the unknown parameters we transform the demand system such that the budget shares occur on the left hand side in (11) and (12). We then add additive error terms. Because of the adding-up restriction, the demand system consisting of (11) and (12) will have an error distribution with a singular covariance matrix. We estimate the parameters

$\beta_{Xj}^1 (j = 1, \dots, m_X)$, γ_{X0i}^1 , γ_{X1i}^1 , $\gamma_{X0U_X^2}^1$ and $\gamma_{X1U_X^2}^1$ by employing iterative multivariate non-linear least squares to the transformed m_X equations in (11). We assume that the error vector has expectation zero and a full covariance matrix. The estimate of the remaining parameter, $\beta_{U_X^2}^1$, is obtained by utilizing the adding-up condition (13). Let us define

$$(14) \hat{\gamma}_{xi}^1 = \hat{\gamma}_{X0i}^1 N + \hat{\gamma}_{X1i}^1 NC, i = 1, \dots, m_X$$

and

$$(15) \hat{\gamma}_{xU_X^2}^1 = \hat{\gamma}_{x0U_X^2}^1 N + \hat{\gamma}_{x1U_X^2}^1 NC.$$

The outlay on necessity consumption at allocation level 1 is given by

$$(16) VXCN^1 = \sum_{i=1}^{m_X} PX_i^1 \hat{\gamma}_{Xi}^1 + PU_X^2 \hat{\gamma}_{xU_X^2}^1.$$

In light of duality theory we may now decompose VXC^1 as

$$(17) VXC^1 = VXCN^1 + PU_X^1 \times U_X^1,$$

where

$$(18) PU_X^1 = \left(\prod_{j=1}^{m_X} \left(PX_j^1 \right)^{\hat{\beta}_{Xj}^1} \right) \left(PU_X^2 \right)^{\hat{\beta}_{U_X^2}^1}$$

and

$$(19) U_X^1 = \left\{ \left[\prod_{j=1}^{m_X} \left(\frac{1}{\hat{\beta}_{Xj}^1} \right)^{\hat{\beta}_{Xj}^1} \right] \left(\frac{1}{\hat{\beta}_{xU_X^2}^1} \right)^{\hat{\beta}_{xU_X^2}^1} \right\} \left[\prod_{j=1}^{m_X} \left(X_j^1 - \hat{\gamma}_{Xj}^1 \right)^{\hat{\beta}_{Xj}^1} \right] \left(U_{xU_X^2}^2 - \hat{\gamma}_{xU_X^2}^1 \right)^{\hat{\beta}_{xU_X^2}^1}.$$

Thus U_X^1 is the utility aggregate at the upper level within branch and PU_X^1 is its companion price index.

Correspondingly, for the other three branches we have $U_Y^1, PU_Y^1, U_Z^1, PU_Z^1, U_W^1$ and PU_W^1 .

We now endogenize the allocation of expenditure on the four branches. For this purpose we again employ the linear expenditure system with demographic effects. Let

$$(20) VTOP = PU_X^1 \times U_X^1 + PU_Y^1 \times U_Y^1 + PU_Z^1 \times U_Z^1 + PU_W^1 \times U_W^1.$$

The demand system written out in volume form at this top level becomes.

$$(21) U_X^1 = \gamma_{x0}^T N + \gamma_{x1}^T NC + \frac{\beta_y^T}{PU_X^1} [VTOP - PU_X^1 (\gamma_{x0}^T N + \gamma_{x1}^T NC) - PU_Y^1 (\gamma_{y0}^T N + \gamma_{y1}^T NC) - PU_Z^1 (\gamma_{z0}^T N + \gamma_{z1}^T NC) - PU_W^1 (\gamma_{w0}^T N + \gamma_{w1}^T NC)],$$

$$(22) U_Y^1 = \gamma_{y0}^T N + \gamma_{y1}^T NC + \frac{\beta_z^T}{PU_Y^1} [VTOP - PU_X^1 (\gamma_{x0}^T N + \gamma_{x1}^T NC) - PU_Y^1 (\gamma_{y0}^T N + \gamma_{y1}^T NC) - PU_Z^1 (\gamma_{z0}^T N + \gamma_{z1}^T NC) - PU_W^1 (\gamma_{w0}^T N + \gamma_{w1}^T NC)],$$

$$(23) U_Z^1 = \gamma_{z0}^T N + \gamma_{z1}^T NC + \frac{\beta_w^T}{PU_Z^1} [VTOP - PU_X^1 (\gamma_{x0}^T N + \gamma_{x1}^T NC) - PU_Y^1 (\gamma_{y0}^T N + \gamma_{y1}^T NC) - PU_Z^1 (\gamma_{z0}^T N + \gamma_{z1}^T NC) - PU_W^1 (\gamma_{w0}^T N + \gamma_{w1}^T NC)],$$

$$(24) U_W^1 = \gamma_{w0}^T N + \gamma_{w1}^T NC + \frac{\beta_x^T}{PU_W^1} [VTOP - PU_X^1 (\gamma_{x0}^T N + \gamma_{x1}^T NC) - PU_Y^1 (\gamma_{y0}^T N + \gamma_{y1}^T NC) - PU_Z^1 (\gamma_{z0}^T N + \gamma_{z1}^T NC) - PU_W^1 (\gamma_{w0}^T N + \gamma_{w1}^T NC)],$$

where

$$(25) \beta_X^T + \beta_Y^T + \beta_Z^T + \beta_W^T = 1.$$

Besides the parameters in (25) the following parameters are involved in (21)-(24):

$$\gamma_{X0}^T, \gamma_{X1}^T, \gamma_{Y0}^T, \gamma_{Y1}^T, \gamma_{Z0}^T, \gamma_{Z1}^T, \gamma_{W0}^T, \gamma_{W1}^T.$$

Again to estimate the involved parameters, at this top level, we transform the system such that the budget shares occur at the left hand side of the equations in (21)-(24). Then we add additive error terms. Because of the adding-up condition the resulting demand system has an error vector with a singular covariance matrix. To obtain estimates of the parameters

$$\gamma_{X0}^T, \gamma_{X1}^T, \gamma_{Y0}^T, \gamma_{Y1}^T, \gamma_{Z0}^T, \gamma_{Z1}^T, \gamma_{W0}^T, \gamma_{W1}^T, \beta_X^T, \beta_Y^T, \beta_Z^T$$

we employ iterative non-linear least squares on the equations (21)-(23), assuming that the errors have a full covariance matrix. The remaining parameter is estimated utilizing the adding up condition (25).

In view of the overall properties of the model some of the initially obtained estimates have been somewhat modified compared to the results from the free estimation. In the following section we report on the estimated/calibrated values when we now continue to the specific setting, in which we are going to use the modelling framework set out in this section.

3. Parameter values in the consumer demand system

3.1. Groceries

This branch may be associated with the X-branch in the previous section. On the lower level expenses on alcoholic beverages are allocated to *Spirits* (*C03C*), *Wine* (*C03D*) and *Bear* (*C03E*). Thus $n_X = 3$.

The accompanying price indices are labelled, respectively, *PC03C*, *PC03D* and *PC03E*.

On the upper level expenses on *Groceries* are allocated to *Food* (*C00*), *Non-alcoholic Beverages* (*C02*), *Tobacco* (*C04*), and to *Alcoholic Beverages*. Thus $m_X = 3$. In Table 1 we report the estimated/calibrated parameter values occurring at the second allocation level within the branch of *Groceries*. Correspondingly, in Table 2 we report estimated/calibrated parameter values occurring at the first allocation level within the branch of *Groceries*.

Table 1. Parameter values in the linear expenditure system for Alcoholic Beverages, allocation level 2 of Groceries

Parameter	Estimated/Calibrated value
$\gamma_{X0,03C}^2$	0.05
$\gamma_{X0,03D}^2$	0.04
$\gamma_{X0,03E}^2$	0.05
$\gamma_{X1,03C}^2$	-0.025
$\gamma_{X1,03D}^2$	-0.025
$\gamma_{X1,03E}^2$	-0.025
$\beta_{X,03C}^2$	0.38
$\beta_{X,03D}^2$	0.37
$\beta_{X,03E}^2$	0.25

Note: All these values correspond to calibrated values.

Table 2. Parameter values in the linear expenditure system at allocation level 1 of Groceries

Parameter	Estimated/Calibrated value
$\gamma_{X0,00}^l$	-0.948
$\gamma_{X0,02}^l$	-0.258
$\gamma_{X0,04}^l$	-1.390
$\gamma_{X0,U_X^2}^l$	-1.087
$\gamma_{X1,00}^l$	7.456
$\gamma_{X1,02}^l$	1.158
$\gamma_{X1,04}^l$	5.772
$\gamma_{X1,U_X^2}^l$	3.821
$\beta_{X,00}^l$	0.500
$\beta_{X,02}^l$	0.150
$\beta_{X,04}^l$	0.140
$\beta_{X,U_X^2}^l$	0.210

Note: While the values of the γ -parameters are estimated parameters the values of the β -parameters correspond to calibrated values.

3.2. Housing

This branch may be associated with the Y-branch in the previous Section. On the lower level heating expenses are allocated to *Electricity for Heating (C12HE)*, *Fossil Fuels (C13A)* and (*C13B*) *Biofuels*. Thus $n_y = 3$. The accompanying price indices are labelled, respectively, *PC12HE*, *PC13A* and *PC13B*. On the upper level expenses on the housing branch are allocated to *Rents (C50)*, *Furniture and Durables (C41)*, *Electrical Appliances (C42)* and *Electricity for Appliances (C12EG)* and to uncommitted heating expenses. With respect to expenses on *Electrical Appliances* and *Electricity for Appliances* we differ somewhat from the specification set out in Section 2. Expenses on *Electrical Appliances* and *Electricity for Appliances* are represented by a CES-aggregate. This CES-aggregate is regarded as the third basic good at allocation level 1. Thus $m_y = 3$. We refer to the CES-aggregate as U_Y^{2*} and its companion price index is given by PU_Y^{2*} . The CES-aggregate and its price index is calculated as

$$(26) U_Y^{2*} = (\hat{\omega}_{42} * (C42/\hat{\omega}_{42})^{**}(-\hat{\sigma}) + \hat{\omega}_{12EG} * (C12EG/\hat{\omega}_{12EG})^{**}(-\hat{\sigma}))^{**}(-1/\hat{\sigma}),$$

$$(27) PU_Y^{2*} = (\hat{\omega}_{42} PC42^{\frac{\hat{\sigma}}{1+\hat{\sigma}}} + \hat{\omega}_{12EG} * PC12EG^{\frac{\hat{\sigma}}{1+\hat{\sigma}}})^{\frac{1+\hat{\sigma}}{\hat{\sigma}}},$$

where *PC42* and *PC12EG* are the price indices accompanying *C42* and *C12EG*, respectively and

$$(28) \hat{\omega}_{42} + \hat{\omega}_{12EG} = 1.$$

The values of $\hat{\sigma}$ and $\hat{\omega}_{42}$ are calibrated to 5 and 0.3, respectively. The demand functions for the two basic goods *C42* and *C12EG* are given by

$$(29) C42 = \hat{\omega}_{42} \left(\frac{PU_Y^{2*}}{PC42} \right)^{\frac{1}{1+\hat{\sigma}}} U_Y^{2*},$$

$$(30) C12EG = \hat{\omega}_{12EG} \left(\frac{PU_Y^{2*}}{PC12EG} \right)^{\frac{1}{1+\hat{\sigma}}} U_Y^{2*}.$$

In Table 3 we report the estimated/calibrated parameter values occurring at allocation level 2 within the branch of *Housing*. Correspondingly, in Table 4 we report estimated/calibrated parameter values occurring at allocation level 1 within the branch of *Housing*.

Table 3. Parameter values in the linear expenditure system for Heating, allocation level 2 of Housing

Parameter	Estimated/Calibrated value
$\gamma_{Y0,I2HE}^2$	0.51913
$\gamma_{Y0,I3A}^2$	-0.23
$\gamma_{Y0,I3B}^2$	-0.023093
$\gamma_{Y1,I2HE}^2$	-1.96315
$\gamma_{Y1,I3A}^2$	1.05769
$\gamma_{Y1,I3B}^2$	0.076716
$\beta_{Y,I2HE}^2$	0.79
$\beta_{Y,I3A}^2$	0.08
$\beta_{Y,I3B}^2$	0.13

Note: The numbers with five decimals are estimated values, and the numbers with two decimals are calibrated values.

Table 4. Parameter values in the linear expenditure system at allocation level 1 of Housing

Parameter	Estimated/Calibrated value
$\gamma_{Y0,50}^l$	-6.28054
$\gamma_{Y0,41}^l$	-3.55077
$\gamma_{Y0,U_Y^2*}^l$	-0.35313
$\gamma_{Y0,U_Y^2}^l$	-0.77475
$\gamma_{Y1,50}^l$	23.5
$\gamma_{Y1,41}^l$	11.75
$\gamma_{Y1,U_Y^2*}^l$	1.5
$\gamma_{Y1,U_Y^2}^l$	2.8
$\beta_{Y,50}^l$	0.565
$\beta_{Y,41}^l$	0.26
$\beta_{Y,U_Y^2*}^l$	0.13
$\beta_{Y,U_Y^2}^l$	0.045

Note: The numbers with five decimals are estimated values, and the numbers with three or fewer decimals are calibrated values.

3.3. Transport

This branch may be associated with the Z-branch in Section 2. On the lower level expenditures related to own transport equipment is allocated to *User Costs of Cars (C31)*, *Maintenance and Spare Parts (C14A)*, *Engine Fuels (C14B)* and *Other Car Expenses (C14C)*. Thus $n_Z = 4$. The accompanying price indices are labelled, respectively, *PC31*, *PC14A*, *PC14B* and *PC14C*. On the upper level expenses on the transport branch are allocated to *Road Transport (C75)*, *Air Transport (C76)*, *Transport by Railway, Tramway and Subway (C77)*, *Transport by Boat and Ferry (C78)*, *Postal and Digital Services (C79)* and uncommitted expenditure on *Private Transport*. Thus $m_Z = 5$.

In Table 5 we report the estimated/calibrated parameter values occurring at the second allocation level within the branch of *Transport*. Correspondingly, in Table 6 we report estimated/calibrated parameter values occurring at the first allocation level within the branch of *Transport*.

Table 5. Parameter values in the linear expenditure system for *Private Transport*, allocation level 2 of *Transport*

Parameter	Estimated/Calibrated value
$\gamma_{Z0,3I}^2$	2.82505
$\gamma_{Z0,I4A}^2$	0.18481
$\gamma_{Z0,I4B}^2$	1.14063
$\gamma_{Z0,I4C}^2$	0.52074
$\gamma_{Z1,3I}^2$	-8.27133
$\gamma_{Z1,I4A}^2$	-0.55473
$\gamma_{Z1,I4B}^2$	-2.61588
$\gamma_{Z1,I4C}^2$	-1.20395
$\beta_{Z,3I}^2$	0.53
$\beta_{Z,I4A}^2$	0.05
$\beta_{Z,I4B}^2$	0.17
$\beta_{Z,I4C}^2$	0.25

Note: The numbers with five decimals are estimated values, and the numbers with two decimals are calibrated values.

Table 6. Parameter values in the linear expenditure system at the allocation level 1 of *Transport*

Parameter	Estimated/Calibrated value
$\gamma_{Z0,75}^l$	1
$\gamma_{Z0,76}^l$	0.37285
$\gamma_{Z0,77}^l$	0.14529

$\gamma_{Z1,75}^l$	-3.43427
$\gamma_{Z1,76}^l$	-1.14766
$\gamma_{Z1,77}^l$	-0.39521
$\gamma_{Z1,78}^l$	-1.02113
$\gamma_{Z1,79}^l$	-1.08190
$\gamma_{Z1,U_Z^2}^l$	-10.48432
$\beta_{Z,75}^l$	0.08
$\beta_{Z,76}^l$	0.035
$\beta_{Z,77}^l$	0.02
$\beta_{Z,78}^l$	0.0408
$\beta_{Z,79}^l$	0.2
$\beta_{Z,U_Z^2}^l$	0.6242

Note: The numbers with five decimals are estimated values, and the numbers with four or fewer decimals are calibrated values.

3.4. Other goods and services

This branch may be associated with the W-branch in the previous Section. In this branch there are no commodities at the lower level, so $n_w = 0$. Expenses on *Other goods and services* are allocated to *Clothing and Footwear (C21)*, *Other Goods (C24)*, *Leisure Goods (C25)*, *Other Services (C65)* and *Direct Purchases Abroad (C66)*. Thus $m_w = 5$. In Table 7 we report estimated/calibrated parameter values occurring in the linear expenditure system of this branch.

Table 7. Parameter values in the linear expenditure system of Other Goods and Services

Parameter	Estimated/Calibrated value
$\gamma_{W0,21}^I$	1.03495
$\gamma_{W0,24}^I$	2.97996
$\gamma_{W0,25}^I$	0.55432
$\gamma_{W0,65}^I$	9.54600
$\gamma_{W0,66}^I$	3.22384
$\gamma_{W1,21}^I$	-2.92433
$\gamma_{W1,24}^I$	-9.00651
$\gamma_{W1,25}^I$	-1.82972
$\gamma_{W1,65}^I$	-29.89217
$\gamma_{W1,66}^I$	-12.10023
$\beta_{W,21}^I$	0.17003
$\beta_{W,24}^I$	0.12432
$\beta_{W,25}^I$	0.14000
$\beta_{W,65}^I$	0.31985
$\beta_{W,66}^I$	0.24580

Note: All the numbers correspond to calibrated values.

3.5. Allocation of non-committed expenditure to the four branches

This may be associated with the top allocation level mentioned in Section 2. In Table 8 we report estimated/calibrated parameter values occurring of the linear expenditure system at this top level.

Table 8. Parameter values in the linear expenditure system at the top allocation level

Parameter	Estimated/Calibrated value
γ_{X0}^T	9.5
γ_{Y0}^T	28
γ_{Z0}^T	4
γ_{W0}^T	25
γ_{X1}^T	-43.6635
γ_{Y1}^T	-108.76500
γ_{Z1}^T	-16.9893
γ_{W1}^T	-109.419
β_X^T	0.11
β_Y^T	0.3
β_Z^T	0.18
β_W^T	0.41

Note: The numbers with three or more decimals are estimated values, and the numbers with two or fewer decimals are calibrated values.

4. Numerical simulation of expenditure and uncompensated and compensated price elasticities

In Appendix C the complete model, which will be used for shift analysis, is written out in the notation used in conjunction with the MSG-model. The model consists of 81 endogenous and 30 exogenous variables. Equations C1-C35 are auxiliary equations defining necessity quantities at different allocation stages and C36-C43 are equations used for defining different price aggregates. These equations constitute a sub block. The endogenous

variables in these equations are only functions of basic prices and demographic variables. The rest of the equations are different demand equations. After having determined the expenses in conjunction with necessity quantities at different allocation levels we can calculate the total expenses in excess of expenditure on the necessity consumption. At allocation level 1 within a specific branch the consumption of basic goods at this allocation level is determined as the sum of necessity consumption and as a share of the excess expenditure allocated to the branch. The expenditure in excess of necessity expenditures of basic commodities occurring at the lowest allocation stage is also determined at this allocation level. At the lowest allocation level consumption of basic commodities is the sum of necessity consumption and expenditure in excess of necessity consumption allocated to the specific basic commodity.

We calculate different price and expenditure elasticities numerically by shift analysis on the model at hand. First, we simulate a reference path for the years 2007–2060.⁶ To calculate uncompensated price elasticities we increase a specific price permanently with one percent from 2007 on. We then look at the percentage change between the target variable in the shift simulation and the reference simulation.

The same procedure is used to simulate expenditure elasticities. Since the elasticities depend on the level of the variables, they will vary according to which year they are calculated. In Table 9 we report the simulated expenditure elasticities and the direct uncompensated and compensated price elasticities for 2007, in tables 10, 11 and 12 we report simulated expenditure elasticities and direct uncompensated and compensated price elasticities for some selected years other than 2007, respectively. In tables F1, F3, F5, F7, F9, F11 and F13 in Appendix F we report simulated uncompensated price elasticity matrices for some selected years. The direct uncompensated price elasticities are written in bold face. Since there are 27 basic commodities the matrices of uncompensated price elasticities have dimension 27×27. Furthermore, in tables F2, F4, F6, F8, F10, F12 and F14 we report matrices with the companion compensated price elasticities. These elasticities are calculated utilizing the Slutsky equations on elasticity form. The budget shares occurring in these formulae are taken from the reference simulation. The direct compensated price elasticities are written in bold face.

⁶ In Appendix G we report the annual growth rates of the exogenous variables for the years 2008–2060. Residuals have been added to the model such that it fits exactly in the base year 2007. The residuals are retained for the entire simulation period.

Table 9. List of commodities. Budget shares, expenditure elasticities and uncompensated and compensated direct price elasticities. 2007^a

^a Elasticities obtained by simulations.^b Biofuels are mostly wood..

Note: The numbers in parentheses provide information about the elasticities according to size among the commodities in the demand system. In each of the three last columns the commodity with the highest absolute value of the elasticity is given rank number 1. The next highest in absolute value is given the value 2, and so on.

In 2007 about half of the commodities have expenditure elasticities that are higher than unity, which means that the average budget shares of these commodities are increasing in total expenditure. However, as seen from Table 9 only four commodities have expenditure elasticities that exceed 1.5.

These three commodities are (i) *Biofuels*, (ii) *Furniture and Durables*, (iii) *Transport by Boat and Ferry* and (iv) *Direct Purchases Abroad*. The three commodities with the lowest expenditure elasticities are (i) *Fossil Fuels*, (ii) *Food* and (iii) *Engine Fuels*. Six of the commodities have direct uncompensated price elasticities exceeding unity in absolute value. Only the commodity *Furniture and Durables* has a direct uncompensated price elasticity that exceeds 1.5 in absolute value. The three lowest direct uncompensated price elasticities are for (i) *Air Transport*, (ii) *Transport by Railway, Tramway and Subway* and (iii) *Fossil fuels*. The level, in absolute value, is in the interval 0.3–0.35.

In the standard one-level LES system (without demographic modifiers) all the Engel elasticities will approach 1, all the uncompensated direct price elasticities will approach -1 and all the uncompensated cross-price elasticities will approach 0. These features are easily seen by inspecting formulae (7)-(9) in Pollak and Wales (1992). The model presented in this specification differs in two respects from the standard one-level LES model. First, we employ a utility tree structure. Second, we have included demographic modifiers. Depending on the assumptions with respect to the demographic development one opens up for the possibility that a substantial time may elapse before one approaches the above mentioned asymptotic values. We see from tables 10 and 11 and the tables in Appendix F how far one is from the asymptotic situation in the selected years ahead.

Table 10. Simulated expenditure elasticities for selected years

Commodity	Year

Notes: For full variable names reference is made to Table 9. The numbers in parentheses provide information about the elasticities according to size among the commodities in the demand system. In each of the columns the commodity with the highest value of the elasticity is given rank number 1. The next highest is given the value 2, and so on.

5. Concluding remarks

In this documentation we have estimated/calibrated a consumer demand system using National Accounts data for the years 1971–2007. We have considered a utility tree structure with four main branches. For this purpose we have utilized Stone-Geary utility functions modified with demographic effects. The applied values of all the parameters have been reported. To assess the properties of the model we have calculated uncompensated and compensated price elasticities and expenditure elasticities. Since the elasticities vary with the data point in which they are evaluated, we report elasticities for different years.

The linear expenditure system is often used in the context of general equilibrium models, but this has not been without criticism. This stems from the restrictive responses attached to this functional form. Among others Australian researchers have in several papers emphasized this, cf. for instance Rimmer and Powell (1996), Cranfield et al. (2000) and Powell et al. (2002) advocating the AIDADS (*An Implicitly Directly Additive Demand System*) specification.⁷ They have demonstrated that it is possible to retain the global regularity properties by the LES and at the same time allow for more flexible responses. However this specification is less parsimonious than the LES specification and more challenging to estimate. Another alternative put forward is the IAS (*Indirect Addilog System*) specification, cf. for instance de Boer and Missaglia (2005), de Boer et al. (2006) and de Boer and Paap (2009). This specification is just as parsimonious as the LES specification, is rather easy to estimate and allows for non-linear Engel curves.

When using consumer demand systems for long run projections one both wants the demand system to behave in a regular manner and at the same time allow for as flexible responses to changes in prices and total expenditure as possible. Unfortunately, commonly used flexible functional forms as translog and AIDS have poor regularity properties, with narrow regular domains. However, some attempts have been carried out aiming at improving the regularity properties of flexible functional forms, cf. for instance Cooper and McLaren (1992, 1996) and McLaren, Fry and Fry (1995).

⁷ Quite recently there also has been launched an alternative to this specification, cf. the MAIDAIDS model of Preckel, Cranfield and Hertel (2010).

Appendix A: Transformation of the LES to share equations and ML estimation

If one divides both sides of (2) with N one obtains

$$(A1) \frac{X_i^2}{N} = \gamma_{X0i}^2 + \gamma_{X1i}^2 NCS + \frac{\beta_{Xi}^2}{PX_i^2} \left[\frac{VX^2}{N} - \sum_{j=1}^{n_X} PX_j^2 (\gamma_{X0j}^2 + \gamma_{X1j}^2 NCS) \right], i = 1, \dots, n_X,$$

where $NCS \equiv \frac{NC}{N}$, i.e. the share of children in the population. Furthermore, let us multiply both sides of the equations by PX_i^2 . This yields

$$(A2) \frac{PX_i^2 X_i^2}{N} = PX_i^2 (\gamma_{X0i}^2 + \gamma_{X1i}^2 NCS) + \beta_{Xi}^2 \left[\frac{VX^2}{N} - \sum_{j=1}^{n_X} PX_j^2 (\gamma_{X0j}^2 + \gamma_{X1j}^2 NCS) \right], i = 1, \dots, n_X.$$

We then divide both sides of (A2) by $\frac{VX^2}{N}$. We then obtain

$$(A3) S_i = QX_i^2 (\gamma_{X0i}^2 + \gamma_{X1i}^2 NCS) + \beta_{Xi}^2 \left[1 - \sum_{j=1}^{n_X} QX_j^2 (\gamma_{X0j}^2 + \gamma_{X1j}^2 NCS) \right], i = 1, \dots, n_X,$$

where $S_i \equiv \frac{PX_i^2 X_i^2}{VX^2}$ and $QX_i \equiv \frac{PX_i^2}{VX^2}, i = 1, \dots, n_X$.

Thus the S_i variables are budget shares and the QX_i variables are normalized prices. If we introduce t as a time index and add error terms (ε_{it}) in (A3) we finally obtain

$$(A4) S_{it} = QX_{it}^2 (\gamma_{X0i}^2 + \gamma_{X1i}^2 NCS_t) + \beta_{Xi}^2 \left[1 - \sum_{j=1}^{n_X} QX_{jt}^2 (\gamma_{X0j}^2 + \gamma_{X1j}^2 NCS_t) \right] + \varepsilon_{it}, i = 1, \dots, n_X, t = 1, \dots, T.$$

Let $\varepsilon_t = [\varepsilon_{1t}, \varepsilon_{2t}, \dots, \varepsilon_{n_X t}]'$. Because of the adding-up identity $\sum_{i=1}^{n_X} s_{it} \equiv 1$, the covariance matrix of ε_t will be singular. One of the equations will be redundant, and let us without loss of generality assume that the last one is omitted. Let the amputated error vector corresponding to the $n_X - 1$ first equations be defined as

$$\varepsilon_t^a = [\varepsilon_{1t}, \varepsilon_{2t}, \dots, \varepsilon_{n_X-1,t}]'$$

We assume that $\varepsilon_t^a \sim N(\underline{0}, \Omega) \forall t = 1, \dots, T$, where $\underline{0}$ is the zero vector and Ω is an unconstrained matrix beyond symmetry. All the parameters with the exception of β_{X,n_X}^2 are estimated by maximizing the log-likelihood corresponding to the $n_X - 1$ first equations in (A4). The estimate of β_{X,n_X}^2 is obtained by utilizing the adding-up condition.

Appendix B: Consumption of own transport equipment

Let $C30_t$ denote purchase of own transport equipment in fixed prices (mostly cars) in year t and $PC30_t$ its associated price index. The stock of own transport equipment is given as the following lag distribution of purchases

$$(B1) \quad HC3I_t = 0.8300 \times C30_t + 0.6889 \times C30_{t-1} + 0.5718 \times C30_{t-2} + 0.4746 \times C30_{t-3} + 0.3939 \times C30_{t-4} + 0.3269 \times C30_{t-5} + 0.2714 \times C30_{t-6} + 0.2252 \times C30_{t-7} + 0.1869 \times C30_{t-8} + 0.1552 \times C30_{t-9} + 0.1288 \times C30_{t-10} + 0.1069 \times C30_{t-11} + 0.0887 \times C30_{t-12} + 0.0736 \times C30_{t-13} + 0.0611 \times C30_{t-14} + 0.0507 \times C30_{t-15} + 0.0421 \times C30_{t-16} + 0.0349 \times C30_{t-17} + 0.0000 \times C30_{t-18}.$$

The depreciation of own transport equipment is given by the dynamic accumulation equation

$$(B2) \quad DC30_t = HC3I_{t-1} - HC3I_t + C30_t.$$

Utilizing (B1) we obtain the following expression

$$(B3) \quad DC30_t = 0.1700 \times C30_t + 0.1411 \times C30_{t-1} + 0.1171 \times C30_{t-2} + 0.0972 \times C30_{t-3} + 0.0807 \times C30_{t-4} + 0.0670 \times C30_{t-5} + 0.0556 \times C30_{t-6} + 0.0461 \times C30_{t-7} + 0.0383 \times C30_{t-8} + 0.0318 \times C30_{t-9} + 0.0264 \times C30_{t-10} + 0.0219 \times C30_{t-11} + 0.0182 \times C30_{t-12} + 0.0151 \times C30_{t-13} + 0.0125 \times C30_{t-14} + 0.0104 \times C30_{t-15} + 0.0086 \times C30_{t-16} + 0.0072 \times C30_{t-17} + 0.0349 \times C30_{t-18}.$$

The depreciation rate may now be calculated as

$$(B4) \quad DC30rate_t = \frac{DC30_t}{(HC3I_{t-1} + C30_t)}.$$

The depreciation rate is approximately constant during the sample period and about 0.17.

Let $r3_t$ denote the after tax real interest rate. It is calculated as

$$(B5) \quad r3_t = (1 - taxpr_t) \times reng_t - q_t,$$

where $reng_t$ denotes the nominal interest rate in year t , $taxpr_t$ the marginal tax rate in year t and q_t expected inflation from year t to $t+1$.

The consumer services of the capital stock in fixed prices are given by

$$(B6) \quad C3I_t = (DCrate30_t + r3_t) \times (HC3I_{t-1} + C30_t).$$

The user cost of capital, $PC30_t \times (DCrate30_t + r3_t)$, is scaled to 1 in the base year. The resulting index is called $PC3I_t$. For practical purposes we have set the nominal interest rate to 8.25 per cent, the marginal tax rate to 0.28 and the expected annual inflation rate to 1.5 per cent in this documentation.

List of figures

Figure 1. The household preference structure in MSG-6 7

List of tables

Table 1.	Parameter values in the linear expenditure system for Alcoholic Beverages, allocation level 2 of Groceries .	11
Table 2.	Parameter values in the linear expenditure system at allocation level 1 of Groceries.....	12
Table 3.	Parameter values in the linear expenditure system for Heating, allocation level 2 of Housing.....	13
Table 4.	Parameter values in the linear expenditure system at allocation level 1 of Housing	13
Table 5.	Parameter values in the linear expenditure system for Private Transport, allocation level 2 of Transport	14
Table 6.	Parameter values in the linear expenditure system at the allocation level 1 of Transport.....	14
Table 7.	Parameter values in the linear expenditure system of Other Goods and Services.....	15
Table 8.	Parameter values in the linear expenditure system at the top allocation level	15
Table 9.	List of commodities. Budget shares, expenditure elasticities and uncompensated and compensated direct price elasticities. 2007a.....	17
Table 10.	Simulated expenditure elasticities for selected years	18
Table 11.	Simulated uncompensated direct price elasticities for selected years.....	18
Table 12.	Simulated compensated direct price elasticities for selected years.....	19
Table D1.	The correspondence between the symbols used in Section 3 and in Appendix C. The expenditure system for alcoholic beverages, allocation level 2 of Groceries	28
Table D2.	The correspondence between the symbols used in Section 3 and in Appendix C. The parameters in the linear expenditure system at allocation level 1 of Groceries	28
Table D3.	The correspondence between the symbols used in Section 3 and in Appendix C. Parameters in the linear expenditure system for heating, allocation level 2 of Housing.....	28
Table D4.	The correspondence between the symbols used in Section 3 and in Appendix C. Parameters occurring in the CES-aggregate of Electrical equipment and electricity used in conjunction with Electrical equipment	29
Table D5.	The correspondence between the symbols used in Section 3 and in Appendix C. The parameters in the linear expenditure system at the upper allocation stage of Housing	29
Table D6.	The correspondence between the symbols used in Section 3 and in Appendix C. The expenditure system related to own transport vehicles, allocation level 2 of Transport.....	29
Table D7.	The correspondence between the symbols used in Section 3 and in Appendix C. The parameters in the linear expenditure system at allocation level 1 of Transport.....	30
Table D8.	The correspondence between the symbols used in Section 3 and in Appendix C. The parameters in the linear expenditure system of Other goods and services.....	30
Table D9.	The correspondence between the symbols used in Section 3 and in Appendix C. The parameters in the linear expenditure system at the top level	31
Table E1.	The correspondence between the variable names used in Section 2 and in Appendix C. The variables occurring at allocation level 2 of Groceries.....	32
Table E2.	The correspondence between the variable names used in Section 2 and in Appendix C. The variables occurring at allocation level 1 of Groceries.....	32
Table E3.	The correspondence between the variable names used in Section 2 and in Appendix C. The variables occurring at allocation level 2 of Housing	32
Table E4.	The correspondence between the variable names used in Section 2 and in Appendix C. The variables occurring at allocation level 1 of Housing	33
Table E5.	The correspondence between the variable names used in Section 2 and in Appendix C. The variables occurring at allocation stage 2 of Transport	33
Table E6.	The correspondence between the variable names used in Section 2 and in Appendix C. The variables occurring at allocation level 2 of Transport.....	33
Table E7.	The correspondence between the variable names used in Section 2 and in Appendix C. The variables occurring in the expenditure system of Other goods and services	34
Table E8.	The correspondence between the variable names used in Section 2 and in Appendix C. The variables occurring in the top level expenditure system	34
Table F1.	Simulated uncompensated price elasticities 2007.....	35
Table F2.	Simulated compensated price elasticities 2007.....	36
Table F3.	Simulated uncompensated price elasticities 2012.....	38
Table F4.	Simulated compensated price elasticities 2012.....	39
Table F5.	Simulated uncompensated price elasticities 2020.....	41
Table F6.	Simulated compensated price elasticities 2020.....	42
Table F7.	Simulated uncompensated price elasticities 2030.....	44
Table F8.	Simulated compensated price elasticities 2030.....	45
Table F9.	Simulated uncompensated price elasticities 2040.....	47
Table F10.	Simulated compensated price elasticities 2040.....	48
Table F11.	Simulated uncompensated price elasticities 2050.....	50
Table F12.	Simulated compensated price elasticities 2050.....	51
Table F13.	Simulated uncompensated price elasticities 2060.....	53
Table F14.	Simulated compensated price elasticities 2060.....	54
Table G1.	Growth rates of exogenous variables in the reference path. 2008–2060. Percent.....	56
