1. Introduction

Regional accounts are a regional specification of the corresponding national accounts. It is composed with the help of a system of distribution keys which allocate the flows of the total economy to the regions. In other words: The accounts are not made by summing up figures based on industry-related statistics for each region, but such statistics will often be the base of the distributing keys.

The national accounts in Norway have integrated supply and use tables showing the supply and use of more than 1000 products and for 180 producing industries and a large number of final users. With some exceptions, each entry in the national supply and use tables are distributed by regions. Regional accounts have been made for several years in Norway. The first regionalisation of the national accounts was accomplished in 1970 for the accounting year of 1965. Since then 8 regional accounts have been made for 1973, 1976, 1980, 1983, 1986, 1990, 1992 and 1993. With the exception of the 1990-accounts, which allocates to municipalities, the regional unit is the county. Thus there are 19 such units plus the extraregio¹. This corresponds to the NUTS 3 (Nomenclature of Territorial Statistical Units) classification of the European Union. Due to methodological and other changes (implementation of new data-sources) over time, the early accounts are not all fully compatible. The last regional accounts of 1992 and 1993 are compatible, due to the fact that the recommendations of Eurostat were implemented for the 1992-accounts.

The accounts of 1993 are constructed with the same methods as the 1992 accounts. However, compensation of employees and net taxes on production have not been distributed by county. This implies that the operating surplus can not be calculated. Final consumption expenditure of households has so far not been allocated to the different counties. On the other hand, we have conducted a pilot project on the regional distribution of household income.

2. Recommendations by Eurostat

The "European System of National and Regional accounts" (ESA 95) chapter 13 contains recommendations for regional accounts. In addition to this two methodological handbooks have been published, Eurostat (1995) and (1996). We will here very briefly sum up some main points of the recommendations:

The statistical unit in the accounts should -as far as possible - be the establishment: the Local Kind of Activity Unit (LKAU). In the Norwegian 1993-accounts this has been followed due to the fact that the LKAU was the unit in the collecting of industry-related statistics and in the business register. For future regional accounts this may prove more difficult. According to the "Council regulation (1996) of Concerning Structural Business Statistics", the main statistical unit should be the firm. It may be a problem that industry-related statistics are recommended to collect less details than what presently are used for the regional accounts

The general principle for location, "The Resident Principle" is that all production and intermediate consumption should be allocated to the region where the producer is resident. If a firm has local kind of activity units in different regions, then each of them should receive the value added in the region where the LKAU can be found. Similarly, for the Gross Fixed Capital Formation (GFCF): Allocation to the region where the investment takes place.

¹ The main activities connected with the oil and gas extraction on the Norwegian Continental Shelf are allocated to the extraregio. The extra-regio is a constructed county, and activities outside the normal counties are allocated here. In addition to the oil- and gas activities, the extra-regio also covers the activity on Svalbard, Jan Mayen, and other economic activity abroad (such as embassies, military units, etc.).

2.1. The implementation of ESA 95: Some specific Norwegian characteristics

For most branches the implementation of the general principle as stated above is straight forward. But there are some exceptions which are not so obvious, and some of them will be discussed below. For a further discussion of the methodological impacts see Edvardsen and Mønnesland (1997).

The allocation of the Gross value added (GVA) in the hydropower industry has followed different patterns over the years. The main trends have been *a)* distribution according to production sites or *b)* distribution according to employment statistics. For some counties of fjords and waterfalls this has an important impact on GVA. In the 1993-accounts the distribution has been separated in two: One part, production of electricity, has been distributed according to the location of the production sites, the production being valued at the local user prices, and the remaining part, mainly distribution services, has been distributed according to employment numbers. Such a division of the industry was possible for the first time in the 1992-accounts.

The transport industries are branches which are not easily regionalised. The location of the production is not unambiguous, due to the nature of these industries. For the railways we have allocated the GVA according to wage shares. For the mid-north county of Nordland we have in addition to this also taken into account the traffic on Ofotbanen, a private railway built for the purpose of transporting iron ore from Kiruna (Sweden) to the harbour of Narvik. In recent years it has also been used for tourism. Another important transport industry to be mentioned is the air traffic. The allocation of the GVA in this industry is divided in two: The gross operating surplus is distributed according to traffic-indicators, and the wages by wage shares.

Fishing is an important activity along the coast of Norway, especially in the Western and Northern parts. Regionalisation of the activity is not obvious, since the activity takes place on the Continental Shelf outside the ordinary counties. There are two possible solutions to the allocation-problem of this industry: Either one can regionalise the GVA to the place of landing the fish, or one can allocate according to the place where the boats are registered. In the 1993-accounts we have followed the procedure that was set in the 1992-accounts: Allocation according to the registered county of the boats. This way the resident-principle as stated above is followed.

A discussion of the principles for regional distribution of the gross domestic product (GDP) should also take product taxes, subsidies and FISIM into account. These are items that are closely linked to production and use of goods and services, and their regional distribution is quite important to regional GDP.

As for product taxes and subsidies, a long debate in Eurostat ended up with a compromise decision to distribute net product taxes in proportion with the regional (total) GVA in basic values. For Norwegian national publications, the regional distribution of production valued at basic prices and the distribution of production valued at producer prices are assumed to be alike. Implicitly, product subsidies and some of the product taxes (not VAT, nor import taxes) are distributed according to the residence of the producer. According to the compromise solution in Eurostat, subsidies of for instance milk would have to be allocated even to counties with no milk production, as Oslo, even though this subsidy in Norway certainly is intended to support the farmers. The Norwegian accounts for 1992 allow for distributing product taxes and - subsidies also according to the use of the products. As described in Edvardsen and Mønnesland (1997), the regional distribution of the Norwegian accounts comes quite close to the distribution according to the Eurostat compromise, whereas distribution according to the residence of the users gives different results, especially for Oslo.

FISIM (Financial Intermediation Services Indirectly Measured) is the interest margins of the financial institutions. In regional accounts prior to 1992 these services were distributed according to the production of the financial institutions. Regarding this item as primarily financial in nature, correcting GVA in the region of production seemed natural. Accepting FISIM as a regular product, regional distribution according to the residence of financial institutions still seems natural as for the part of the

product that is considered final use of the product. Deliveries for intermediate consumption should be distributed according to the residence of the users. As the financial institutions of Norway are heavily concentrated in Oslo, distribution according to total GVA, as presently used, gives a more even distribution of FISIM than distribution according to the production of financial services. The regional concentration of GVA to Oslo increased as a result of the new principle of regionalisation implemented from 1992 on.

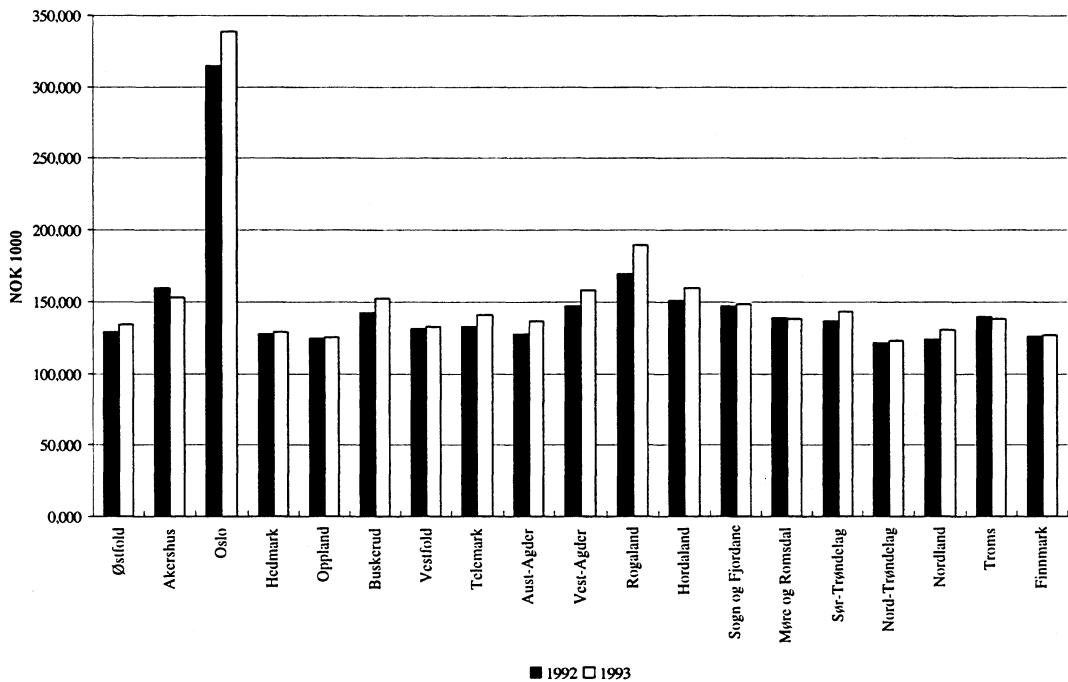

Regional distribution of non-produced transactions; from GVA to RGDP:

Value added tax (VAT), taxes on investment, customs duties, other taxes on imported products and FISIM are allocated to regions according to total GVA, and not allocated to the different industries. Regional Gross Domestic Product (RGDP) is the sum of GVA, net taxes on production less FISIM.

3. Main results, Norwegian regional accounts 1993

The main results of the 1993 accounts are given in table 1. Figure 1 below illustrates how the RGDP varies between the counties, and comparisons are made with the numbers for 1992.

Figure 1: RGDP per inhabitant 1992 and 1993. Norewegian counties

The main structure remains the same from 1992 to 1993: The capital county of Oslo has the highest RGDP per inhabitant, followed by the oil- and gas-dominated Rogaland.

As can be seen of the indices in table 1, Oslo has more than twice as high RGDP per inhabitant as the national average. One main explanation is the commuting to Oslo from the neighbouring counties. The index for RGDP per employed person takes commuting into account, and now we see that the index for Oslo is much lower. The counties whose workers are commuting to Oslo have higher indices per employee than per inhabitant.

Still, RGDP per employee for Oslo is 29 per cent higher than the national average. Rogaland also has a high index: 11 per cent more than the country average. Finnmark, the most northern county, has the lowest index: 21 per cent below the country-average. Oppland, a mid-south inland county, and Sogn og Fjordane, a county of fjords at the western coast both have an index value 16 per cent below the country average.

3.1 Structural differences between the industries in the different counties

To find some of the reasons behind the differences we have to look at the compilation of industries in the different counties. We have found that, on the average, a person employed in manufacturing industries contributes to the total GVA with NOK 346 600. Whereas a person employed within service industries contributes to GVA with NOK 319 900. The contribution is lowest for workers within agricultural industries: NOK 199 100 on the average. Figure 2 illustrates the composition of the GVA, divided in these main industries. Total GVA is 100 per cent for each county. When comparing this figure with the table above we can see that the counties with the low RGDP, have

relatively high shares of agricultural activities. Nord-Trøndelag has the highest share: 9.6 per cent of the county's GVA comes from agricultural activities. The inland counties of Hedmark and Oppland also have high shares of agricultural activity: 8.6 and 6.8 per cent of the GVA.

The highest shares of Industrial activities are found for the counties of Telemark and Rogaland; Industrial activities contribute with approximately 37 per cent of the total GVA for these counties.

Naturally, services have their largest shares of GVA in counties with the largest cities. In Oslo services account for 87 per cent of the total GVA. The share of services in Akershus is 81 per cent. As can be seen from the figure, Troms, Sør-Trøndelag and Hordaland also have high shares of services.

Figure 2: The composition of GVA. Norwegian counties 1993

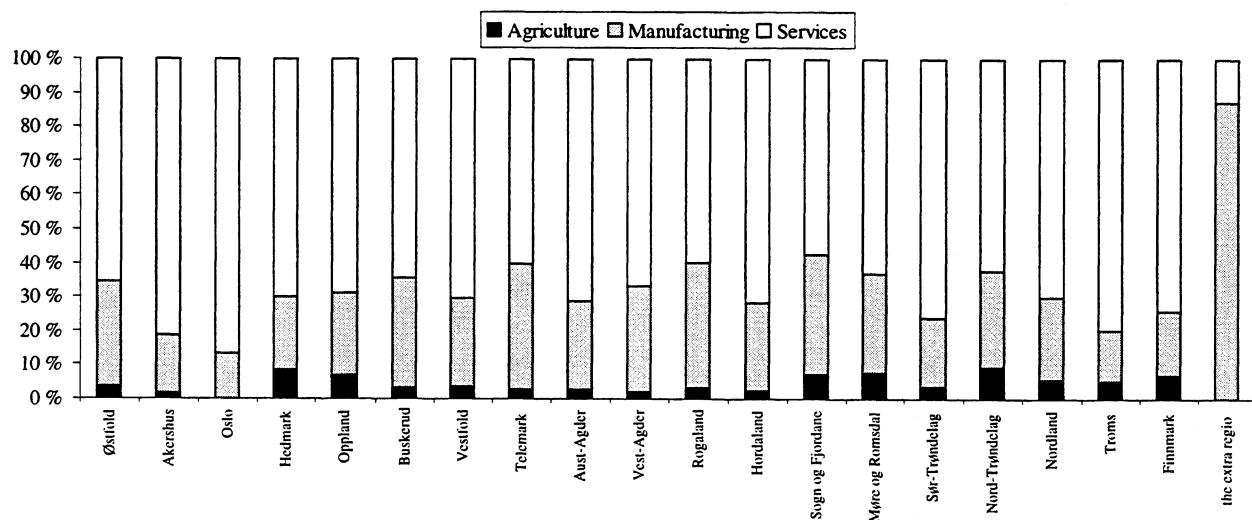

Table 2 gives indices per employed person occupied in these main economic activities. For each group the country average is 100, so this table gives a more differentiated picture, and can in a very simplified manner demonstrate differences in productivity between the counties.

As can be seen from table 2, the indices vary a lot within each county, depending on each county's comparable advantages in the main activities.

Table 2: GVA per employed person in main activities.**Index, the whole country, ordinary counties = 100. Norwegian counties 1993**

	<i>Primary industries</i>	<i>Secondary industries</i>	<i>Services</i>

3.2 General government versus market production

Each county's total GVA can also be divided by category. Hereby we distinguish:

1. Production for own final use
2. Market production and non-market production of non-profit institutions serving households
3. Non-market production of local government
4. Non-market production of central government

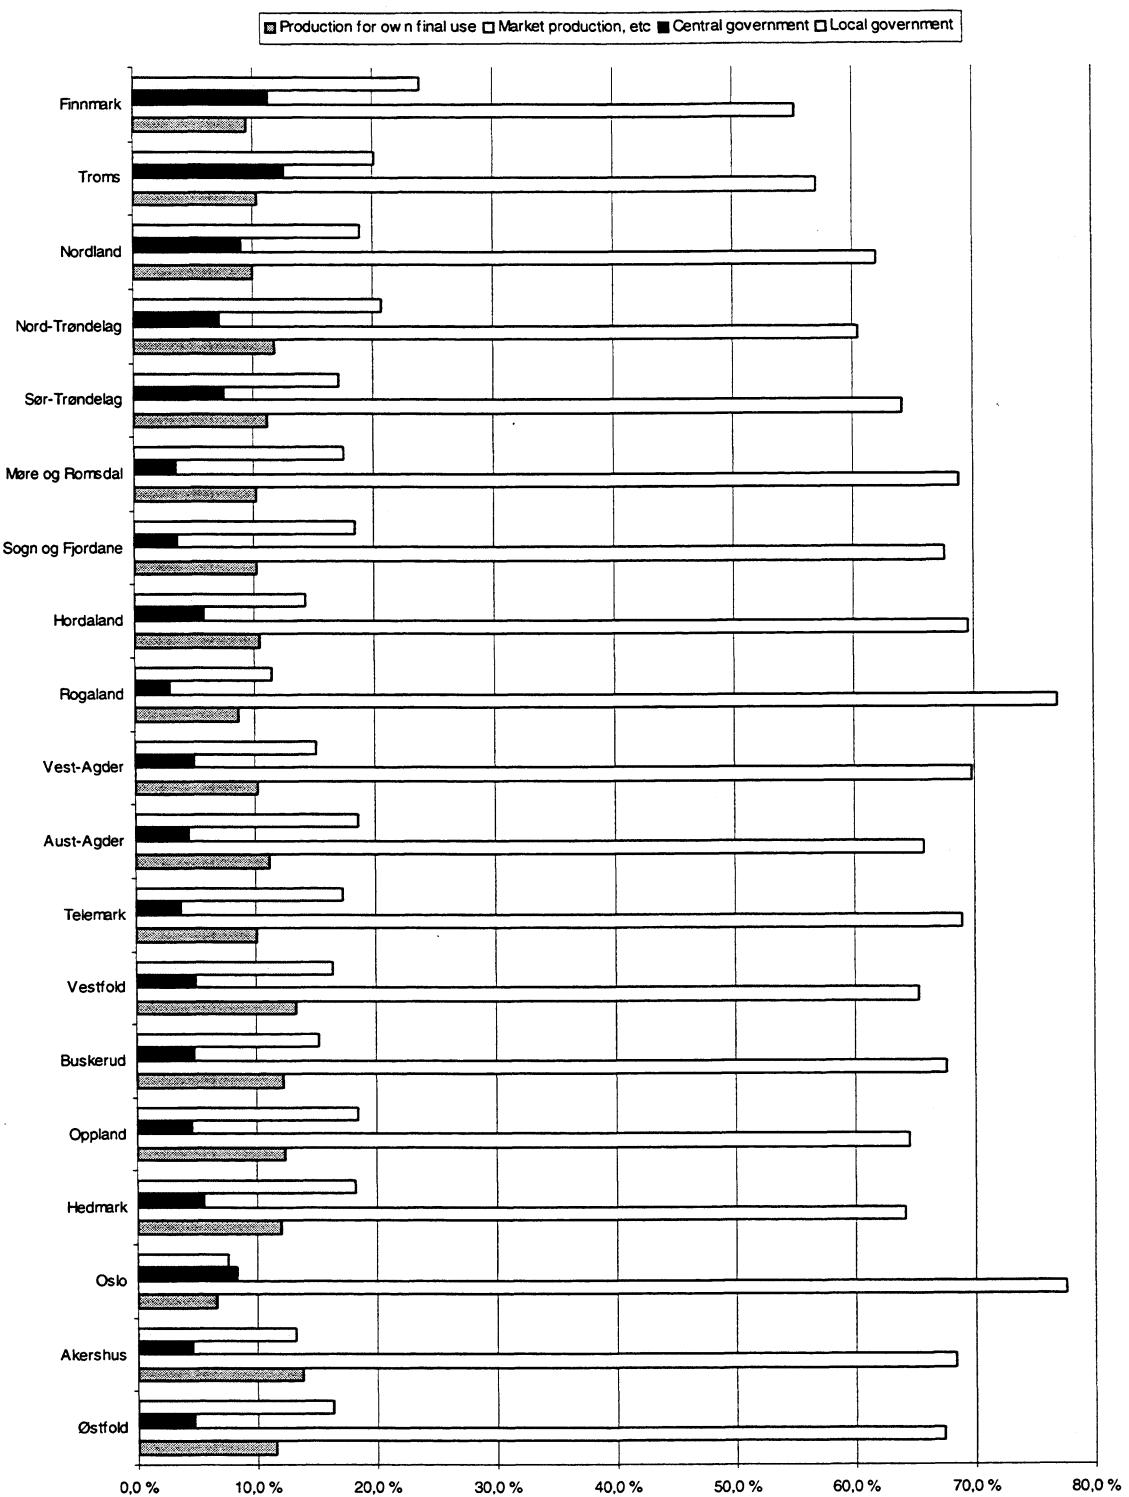

Norway is considered a welfare-state, in the sense that the public sector has large responsibilities to the inhabitants. This has implications for the relative size of the government production (here: the sum of central and local government). Obviously, for some counties, the government production is of more importance than for other counties. We know for instance that 29 per cent of the GVA from Government services is produced in Oslo. But this alone would not tell us anything about the impact of government services on Oslo's total GVA. This can be seen from figure 3. Government services' contribution to the total GVA of Oslo is approximately 8 per cent. The largest shares of the counties' GVA are to be found for market-production and non-market production of non-profit institutions serving households². These shares vary a lot between the counties. Oslo and Rogaland have high shares of market production; more than 80 per cent of the total GVA. For most counties market production accounts for more than 70 per cent of the county's total GVA, from 79 per cent in Hordaland to 71 per cent in Nord-Trøndelag. We have two exceptions: the northernmost counties of

² As a simplification, the category "production and non-market production of non-profit institutions serving households" is in this document also referred to as "market production".

Troms and Finnmark. Market production measured as a share of total GVA is 57 per cent in Troms, and 55 per cent in Finnmark. In accordance with this one can observe that the same counties have the largest shares of central government. For Troms central government accounts for 11 per cent of the county's total GVA, for Finnmark the share is 13 per cent.

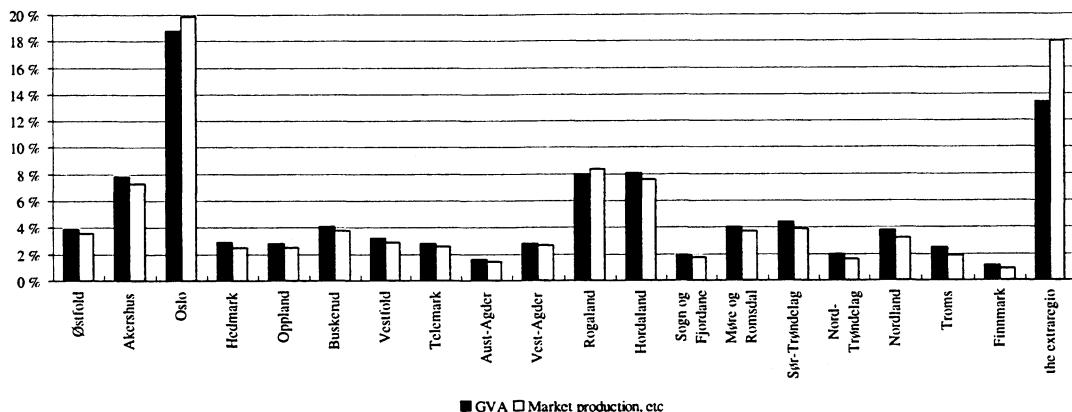

In Norwegian functional accounts, services produced in general government sector are recorded separately from services produced by NPISHs of market producers. This can be used to define government production, as the production activities of (non-market) units belonging to general government, including health and education services, as well as government administration.

Figure 3: GVA by category type of producer, each county = 100 %

Comparisons can also be made between the counties' share of total GVA and shares of the total market production. The result is given in figure 4.

Figure 4: Norwegian counties' shares of GVA and market production

With the exception of the extraregio, there are only two counties that have a larger share of market-production than of total GVA: Oslo and Rogaland. The difference between the shares is very small for all counties, but largest for the northernmost counties, and for Akershus.

3.3 Regional distribution of investment

We will now take a closer look at the regional distribution of the gross fixed capital formation, GFCF. The aggregated numbers for the distribution of GFCF are given in table 1. In table 3 two comparisons are made:

- a) GFCF as share of the counties total RGDP, noted I_{own}
(each county's RGDP = 100 per cent), and
- b) The county's share of total GFCF for the whole country, $I_{country}$
(GFCF for the whole country = 100 per cent).

At first sight the discrepancies between $I_{country}$ and the counties' share of total GDP seem small. But there are still some differences, particularly significant for the counties of Oslo and Rogaland. Oslo has a much smaller share of the total GFCF (12 per cent) than the share of GDP (20 per cent), and vice versa for Rogaland; Rogaland's share of GDP is rather small (8 per cent), compared with its share of GFCF (22 per cent). Rogaland's location, as a main landbase for much of the activity on the continental shelf, must serve as an explanation to this. The investments in the oil industry reached a maximum in 1993, and as can be seen in table 4, 30 per cent of total GFCF for Norway was located to the extraregio.

Comparing the first and the last column in table 3, we may get an idea of future perspectives, and it will be interesting to compare these numbers over time. We see that, in this particular accounting year, some of the less rich counties, measured by their shares of total GDP, had large investment shares, measured as shares of the county's own RGDP, I_{own} . At this moment, based on limited material, it is impossible to state whether these are normal variations, or the expression of a trend.

Table 3: Regional distribution of GFCF. Per centages. Norwegian counties 1993

	GFCF's share of each county's RGDP <i>I_{own}</i>	The counties' share of total GFCF <i>I_{country}</i>	The counties' share of total GDP

the extraregio	49	30	12

4. Statistical sources

In general, industry-related statistics have been preferred as the source of the regional distribution keys. Such statistics are available for agriculture, forestry, fishing, mining and manufacturing, most business services, hotels and restaurants and for local government and occasionally some other small industries. For most of these statistics the statistical unit is the local kind of activity unit.

In other branches such statistics can not be utilized (this may be due to availability, lack of compatibility and/or consistency, reliability, etc.). In such cases general register sources are used. The registers used are:

- [1] *Central Register of Establishments (BOF).*
The register covers, with a few exceptions, all industries. It contains data for turnover and employment. The register is continuously updated. The quality, however, varies between the industries.
- [2] *The Register of wages and salaries (LTO).*
Employers are obliged to report wages and salaries of each of their employees to this tax-related register. There is no industry classification on the reporting unit, so the register has been matched with the register for employers/employees to get the industry classification. Certain quality problems are acknowledged, especially for central government. The industry classification of the employment registers was, however, not revised until the 1996 statistics, whereas the national accounts follow the NACE rev. 1 from 1992 on.

[3] *The Registers of Civil Servants (SST and STS)*

This includes sums of wages and salaries and the budget code to be used in the Central Government, fiscal accounts. These budget codes are the basis for classification by industry. For the year 1993, these registers also cover the wages and salaries for market producers owned by the Central government, such as Post and telecommunications, railways and some financial institutions owned by the central government.

We will give a brief description of the distribution of production, intermediate consumption, gross fixed capital formation and employment.

4.1 Distribution of production, intermediate consumption and investments

Unless specified, intermediate consumption and investment (GFCF) have been allocated to counties according to production.

Regional distributions of crops and several other products have been used to allocate the output from agriculture, forestry and fishing. As for fishing, the output has been redistributed as earlier mentioned: according to the register county of the boats. Intermediate consumption of fish farms and hatcheries has been allocated due to industry-related statistics. A special calculation is applied for intermediate consumption of concentrated feed within agriculture. For fish farming there also exists a regional distribution of investment, which has been used to distribute the GFCF .

The output from oil and gas extraction has been allocated according to manufacturing statistics. These statistics also include distributions of the GFCF, which has been used. Intermediate consumption is distributed according to the production.

Every forth year there is a total counting of the use of raw materials in mining and manufacturing. This was done for 1993, thus providing us with more information than usual. The use of this information in intermediate consumption and GFCF gives added quality to these numbers, compared with earlier accounts.

Electricity production has been discussed in Ch. 2. The production is allocated due to production statistics, whereas transportation and distribution of electricity are allocated according to wage sums from the LTO-register. For district heating, primary statistics that cover production, intermediate consumption and investments are available. The production of water supply is distributed based on statistics given by the local governments accounts.

In the construction industry the distribution of output and intermediate consumption is taken in two steps: First; allocation according to the BOF-register. Then; when the total gross fixed capital formation (GFCF) as well as repairs etc. are distributed by region, the production and intermediate consumption are reallocated on the basis of the total use of the products from the construction industry.

Industry-related statistics on turnover and calculated trade margins are used to distribute production and intermediate consumption for retail and wholesale. The trade margins were from 1992. GFCF has been distributed on the basis of data on investment levy. The output in repairing industries is allocated according to turnover from the BOF-register.

The SST-register is used to allocate the production within post, telecommunications and railways, as already mentioned in Ch.2. Primary statistics and local business accountings are used for the distribution of the production within transportation by tram and subways. Primary statistics have also been used to allocate production in the bus, taxi, and other land transportation industries. For air

transport the wage sums from the LTO-register are combined with traffic data, see ch. 2. For services in connection to air transport we have also received special data on the investment. The BOF-register was used to allocate production from tourist buses, inland water transport, travel agencies and other services in connection with transportation, with the exception of port authorities, where financial accounts are used. Investment in hotels is distributed according to building statistics.

The production of financial intermediation services are distributed according to wage sums in the LTO-register.

Like the accounts for 1992, dwelling services have been subject to special calculations, based on building statistics, analysis of prices on used dwellings, and broad regional (5 regions) data on rents in relation to the value of the housing stock. Investments in dwellings are distributed according to building statistics.

The production in renting and industrial cleaning services is distributed according to the BOF-register. For other business services industry-related statistics have been used to allocate production, intermediate consumption and GFCF.

Production of other services are distributed according to wage sums in the LTO-register.

Registerdata from SST/STS are used to allocate the output from education.

The production of radio and television, cinemas and other entertainment and cultural services is distributed according to the employment in the BOF-register.

Local government accounts have been the basis for distributing the output and intermediate consumption of local government. For defence, the data are summary updates for 1992 from the defence administration. Central government is distributed using wage data from the registers of civil servants.

4.2 Regional distribution of employment

The Annual National Accounts give the average sum of employed persons throughout the year. Part-time workers and occasional absentees are included. There is a survey of agriculture for 1993 (also used for 1992), which provides data on distributions of employment and self-employed persons in agriculture and forestry. Employment in fishing is covered by a register of fishermen. For other industries the number of self-employed persons has been subject to special calculations of the BOF-register. Industry-related statistics cover the employment in mining and manufacturing, business services, local and central government, fish farming and oil and gas extraction. To ensure consistency in the regional distributions, the BOF-register has been used as a source for distributed employment for those industries whose other regional distributions are based upon this register. For the rest of the industries, the register of wages and salaries (LTO) is the source.

4.3 The use of the tables

In order to ensure anonymity, it has been necessary to withhold some figures from publication. The rule is that publication of numbers is only allowed if three or more companies are present in the single county/single industry. Further disclosure is needed if the numbers could be calculated as residuals. The disclosed figures are included in the published sums. It is mostly within manufacturing that such problems arise.

Transport equipment	35(-35.114,-35.115), 34
Furniture, other manuf., recycling	36, 37
Electricity, gas and water supply	40, 41
Construction	45
Wholesale and retail trade	50.1, 50.3, 50.5, 51, 52.1-52.6
Repair of motor vehicles and goods	50.2, 50.4, 52.7
Hotels and restaurants	55
Inland water transport etc.	61.103-61.109, 612, 63.112, 63.22, 63.402
Ocean transport	61.101, 61.102
Transport via pipelines	60.3
Other transport activities	60(-60.3), 62, 63(-63.112, -63.22,-63.402)
Post and telecommunications	64
Financial intermediation	65, 66, 67
Real estate activities	70
Renting and business activities	71, 72, 73, 74
Public administration and defence	75
Education	80
Health and social work	85
Services n.e.c.	90 - 95
<u>Agricultural activities:</u> Agriculture, hunting, forestry and fishing	01-05
<u>Industrial activities:</u> Oil and gas extraction, mining and quarrying, manufacturing electricity, gas and water supply, construction	10-49
<u>Services:</u> Service activities	50-95
